FLOOD LENS / SITUATION REPORT

Trishuli river corridor

Event date: 2026-08-26 | Mode: LIVE

Flood extent

Mapped potential new inundation covers 0.195 km2. Possible debris or land-cover change covers 0.000 km2. Usable radar coverage is 13.6%; paired clear optical coverage is 31.1%. No detected change does not establish absence of damage.

Infrastructure exposure

The mapped changes intersect 0 buildings, 1 road features and 1 bridges. Intersecting road length is 0.032 km. Exposure does not establish structural damage.

Road access

Assuming exposed road segments are impassable, 0 settlements lose their previous connection to every mapped town or hospital: none identified. 17 settlements could not be assessed. Routes outside the analysis area are unknown.

Data provenance

Radar acquisitions: 2026-08-16T12:21:53.557589Z and 2026-08-28T12:21:54.261291Z; both use relative orbit 85 (ascending). Historical OpenStreetMap snapshot: 2026-07-27T08:59:58Z. All counts come from saved map intersections and road-graph analysis. Terrain: Copernicus DEM GLO-30. Optical: Sentinel-2. Water-model training: Kuro Siwo and Sen1Floods11.

Limitations

This educational prototype cannot give minute-ahead warnings. Radar shadow, layover, vegetation, cloud, seasonal changes and incomplete OSM roads can affect results. Exposure and road interruption are hypotheses requiring field verification. Population and casualty estimates are unavailable. The initial model has low held-out recall on Kuro Siwo; damage outside usable coverage remains unknown.
